Abstract

Given a ring $C$ and a totally (resp. partially) ordered set of “monomials” $\mathcal{M}$, Hahn (resp. Higman) defined the set of power series $C[[\mathcal{M}]]$ with well-ordered (resp. Noetherian or well-quasi-ordered) support in $\mathcal{M}$. This set $C[[\mathcal{M}]]$ can usually be given a lot of additional structure: if $C$ is a field and $\mathcal{M}$ a totally ordered group, then Hahn proved that $C[[\mathcal{M}]]$ is a field. More recently, we have constructed fields of “transseries” of the form $C[[\mathcal{M}]]$ on which we defined natural derivations and compositions.

In this paper we develop an operator theory for generalized power series of the above form. We first study linear and multilinear operators. We next isolate a big class of so-called Noetherian operators $\Phi: C[[\mathcal{M}]] \to C[[\mathcal{N}]]$, which include (when defined) summation, multiplication, differentiation, composition, etc. Our main result is the proof of an implicit function theorem for Noetherian operators. This theorem may be used to explicitly solve very general types of functional equations in generalized power series.

1 Introduction

In [Hah07], Hahn introduced an abstract framework for algebraic computations on power series with generalized exponents like

$$f = 1 + z^{\log 2} + z^{\log 3} + z^{\log 4} + \cdots ;$$
$$g = 1 + z + z^2 + z^e + z^3 + z^{1+e} + z^4 + z^{2+e} + z^5 + z^{2+e} + z^{3+e} + \cdots ;$$
$$h = 1 + z^{1/2} + z^{3/4} + z^{7/8} + \cdots + z^{3/2} + z^{7/4} + \cdots + z^2 + \cdots + \cdots .$$

One of his main results states that, given a field $C$ and a totally ordered monomial group $\mathcal{M}$, the set $C[[\mathcal{M}]]$ of series $f: C \to \mathcal{M}$ with well-ordered support in $\mathcal{M}$ carries a natural field structure. This result was generalized by Higman [Hig52] to the case of partially ordered monomial monoids $\mathcal{M}$.

More recently, Dahn and Göring [DG86] and Écalle [É92] constructed so-called fields of “transseries”, which are fields of generalized power series $C[[\mathcal{M}]]$ in the sense of Hahn, with additional structure, such as exponentiation, differentiation, integration, composition, etc. Examples of transseries are

$$\varphi = x + \log x + \log \log x + \log \log \log x + \cdots ;$$
$$\psi = e^{x + e^{x/2} + e^{x/3} + \cdots} + e^{e^{x/2} + e^{x/3} + e^{x/4} + \cdots} + e^{e^{x/3} + e^{x/4} + e^{x/5} + \cdots} + \cdots ;$$
$$\xi = \Gamma(x) = \sqrt{2\pi} e^{x \log x - x - \frac{1}{2} \log x} + \cdots .$$

In [vdH97], we have shown how to differentiate, integrate and compose such transseries, and how to solve algebraic differential equations (whenever possible).
In this paper, we will be concerned with the development of an abstract operator theory for generalized power series, in the setting of partially ordered monomial sets introduced by Higman. We start by recalling some basic results about Noetherian orderings (also called well-quasi-orderings) in section 2. In Higman’s setting, generalized power series have Noetherian support. For this reason, we shall actually call them Noetherian series.

In section 3, we recall the definition of Noetherian series and develop the theory of strongly linear and strongly multilinear operators. More precisely, it is possible to define a notion of infinite summation on algebras $C[[M]]$ of Noetherian power series. One may think of this as something analogous to normal summable families in analysis. Strongly linear mappings will then be linear mappings which also preserve infinite summation.

The remainder of this article focuses on the resolution of certain functional equations. Translated into the terminology of operators, this comes down to the isolation of nice classes of operators on which some kind of implicit function theorem holds (actually, we will rather prove “parameterized fixed point theorems”). As a basic example, one would like to solve implicit equations like

$$f = g + f' f''$$

in fields of transseries, where $g$ is a sufficiently small parameter (say $g = o(e^{-x})$) and $f$ the unknown.

In section 4, we start by developing a theory of continuous and contracting functions for Noetherian series and we will prove the existence of a solution $f = \Psi(g)$ to equations like (1) using the technique of fixed points. Actually, we will prove an implicit function theorem which is very similar to fixed point theorems from [PC90] and [PCR93], although our proof is more constructive.

A more natural and even more explicit way of getting solutions to (1) would be to replace the left hand side by the right hand side in a recursive manner, while expanding all sums. This would lead to a formal solution of the form

$$f = g + f' f'' = g + g' g'' + (f' f'')' g'' + g' (f' f'')'' + (f' f'')' (f' f'')'' = g + g' g'' + (g' g'')' g'' + g' (g' g'')'' + \ldots.$$  

The main difficulty then resides in proving that the obtained formal expansion is indeed summable in our generalized sense. In sections 5 and 6, we will prove that this is indeed the case for a suitable class of “Noetherian operators”.

## 2 Noetherian orderings

Throughout this paper, orderings are understood to be partial, except when we explicitly state them to be total. Actually, almost all ordered sets considered in this paper are monomial sets, and we denote them by fraktur letters $\mathfrak{M}, \mathfrak{N}, \ldots$. We denote by $(\supseteq, \supseteq_M, \supseteq_N, \ldots)$ the orderings on such monomial sets. Usually, $\mathfrak{M}$ is even a monomial monoid or group, on which the multiplication is assumed to be compatible with the ordering, i.e.

$$m \lessdot n \iff m v \lessdot n v \iff v m \lessdot v n,$$

for all $m, n, v \in \mathfrak{M}$.

### Example 1.

1. $\mathfrak{M} = \{x^\alpha e^{\beta x} | \alpha, \beta \in \mathbb{R} \}$ with $x^\alpha e^{\beta x} \succ 1 \iff (\beta > 0 \lor (\beta = 0 \land \alpha > 0))$ is a totally ordered monomial group.
Let us first establish some characterizations of Noetherian orderings.

Proposition 3. Let $\mathcal{M}$ and $\mathcal{N}$ be monomial sets, then their disjoint union $\mathcal{M} \sqcup \mathcal{N}$ is naturally ordered, by taking the orderings on $\mathcal{M}$ and $\mathcal{N}$ on each part of the disjoint union, and by taking $\mathcal{M}$ and $\mathcal{N}$ mutually incomparable in $\mathcal{M} \sqcup \mathcal{N}$.

Remark 2. In the literature, an ordered set $(E, \preceq)$ is usually said to be well-founded, if there are no infinite sequences $x_1 > x_2 > \cdots$ of elements in $E$. This definition is compatible with ours, if one interprets a monomial set $\mathcal{M}$ to be ordered by the opposite ordering $\succeq$ of $\preceq$ (as we did).

Let $\mathcal{M}$ be a monomial set. A chain in $\mathcal{M}$ is a subset of $\mathcal{M}$ which is totally ordered for the induced ordering. An antichain is a subset of $\mathcal{M}$ of pairwise incomparable elements. The ordering on $\mathcal{M}$ is said to be well-founded, if there are no infinite sequences $m_1 < m_2 < \cdots$ of elements in $\mathcal{M}$. A Noetherian ordering is a well-founded ordering without infinite antichains.

Proposition 3. Let $\mathcal{M}$ be a monomial set. Then the following are equivalent:

a) The ordering $\succeq$ on $\mathcal{M}$ is Noetherian.

b) Any final segment of $\mathcal{M}$ is finitely generated.

c) The ascending chain condition w.r.t. inclusion holds for final segments of $\mathcal{M}$.

d) Each sequence $m_1, m_2, \ldots \in \mathcal{M}$ admits a subsequence $m_{i_1} \succeq m_{i_2} \succeq \cdots$.

e) Any extension of the ordering on $\mathcal{M}$ to a total ordering on $\mathcal{M}$ yields a well-ordering.

The most elementary examples of Noetherian orderings are well-orderings, and orderings on finite sets. Proposition 3 allows us to construct more complicated Noetherian orderings from simpler ones:

Proposition 4. Assume that $\mathcal{M}$ and $\mathcal{N}$ are Noetherian monomial sets. Then

a) Any subset of $\mathcal{M}$ with the induced ordering is Noetherian.

b) Let $\mathcal{M} \rightarrow \mathcal{V}$ be an increasing mapping into a monomial set $\mathcal{V}$. Then $\text{Im} \ \varphi$ is Noetherian.

c) Any extension of the ordering $\succeq$ on $\mathcal{M}$ is Noetherian.

d) $\mathcal{M} \sqcup \mathcal{N}$ is Noetherian.

e) $\mathcal{M} \times \mathcal{N}$ is Noetherian.
The following theorem is due to Higman [Hig52]. We will recall a proof due to Nash-Williams [NW63], because a similar proof technique will be used in section 6.1.

**Theorem 5.** Let \( \mathcal{M} \) be a Noetherian monomial set. Then \( \mathcal{M}^* \) is Noetherian.

**Proof.** We say that \( n_1, n_2, \ldots \) is a bad sequence in \( \mathcal{M}^* \), if there do not exist \( i < j \) with \( n_i \succ \succ \mathcal{M} n_j \). An ordering is Noetherian if and only if there are no bad sequences. Now assume for contradiction that \( n_1, n_2, \ldots \) is a bad sequence in \( \mathcal{M}^* \). Without loss of generality, we may assume that each \( n_i \) is chosen in \( \mathcal{M}^* \setminus \{n_1, \ldots, \} \) such that it has minimal length as a word. We say that \( n_1, n_2, \ldots \) is a minimal bad sequence.

Now for all \( i \), we must have \( n_i \neq \varepsilon \), so we can factorize \( n_i = m_i u_i \), where \( m_i \) is the first letter of \( n_i \). By proposition 3(d), we can extract a sequence \( m_{i_1} \succ \succ \mathcal{M} m_{i_2} \succ \succ \mathcal{M} \ldots \) from \( m_1, m_2, \ldots \). Now consider the sequence \( n_{i_1}, \ldots, n_{i_{1-1}}, u_{i_1}, u_{i_2}, \ldots \). By the minimality of \( n_1, n_2, \ldots \), this sequence is good. Hence, there exist \( j < i_1 \) and \( k \) with \( n_j \succ \succ \mathcal{M} v_{i_k}, \) or \( j < k \) with \( v_{i_j} \succ \succ \mathcal{M} v_{i_k} \). But then, \( n_j \succ \succ \mathcal{M} v_{i_k} \succ \succ \mathcal{M} v_{i_k} v_{i_k} = n_{i_k} \) resp. \( n_{i_j} = m_{i_j} v_{i_j} \succ \succ \mathcal{M} m_{i_k} v_{i_k} = n_{i_k} \). This contradicts the badness of \( n_1, n_2, \ldots \). □

### 3 Noetherian series

#### 3.1 Noetherian series and infinite summation

Let \( C \) be a commutative group of coefficients and \( \mathcal{M} \) a set of monomials. The support of a mapping \( f: \mathcal{M} \to C \) is defined by

\[
\text{supp } f = \{ m \in \mathcal{M} | f(m) \neq 0 \}.
\]

If \( \text{supp } f \) is Noetherian for the induced ordering, then we call \( f \) a generalized power series or a Noetherian series. We denote the set of all Noetherian series with coefficients in \( C \) and monomials in \( \mathcal{M} \) by \( C[[\mathcal{M}]] \). We also write \( f_m = f(m) \) for the coefficient of \( m \in \mathcal{M} \) in such a series and \( \sum_{m \in \mathcal{M}} f_m m \) for \( f \). Each \( f_m m \) with \( m \in \text{supp } f \) is called a term occurring in \( f \).

Given two Noetherian series \( f, g \in \mathcal{M} \), we define their sum by

\[
f + g = \sum_{m \in \text{supp } f \cup \text{supp } g} (f_m + g_m) m.
\]

This gives \( C[[\mathcal{M}]] \) the structure of a commutative group. More generally, consider a family \( (f_i)_{i \in I} \) of series in \( C[[\mathcal{M}]] \). We say that \( (f_i)_{i \in I} \) is a Noetherian family, if \( \bigcup_{i \in I} \text{supp } f_i \) is Noetherian and for each \( m \in \mathcal{M} \) there exist only a finite number of \( i \in I \) such that \( m \in \text{supp } f_i \). In that case, we define its sum by

\[
\sum_{i \in I} f_i = \sum_{m \in \mathcal{M}} \left( \sum_{i \in I} f_{i,m} \right) m. \tag{2}
\]

This sum is again a Noetherian series. In particular, given a series \( f \in C[[\mathcal{M}]] \), the family \( (f_m m)_{m \in \text{supp } f} \) is Noetherian and we have \( f = \sum_{m \in \text{supp } f} f_m m \) in the sense of (2).

It is useful to see \( C[[\mathcal{M}]] \) as a strong commutative group, i.e. a commutative group with an additional “infinite summation structure” on it. In our case, this structure is reflected through the infinite summation of Noetherian families; it satisfies the following fundamental properties:

**Proposition 6.**

- a) Any zero family \( (0)_{i \in I} \) is Noetherian, and \( \sum_i 0 = 0 \).
b) For any \( f_i \in [[\mathcal{M}]] \), the family \((f_i)_{i \in \{1\}}\) is Noetherian, and \( \sum_{i \in \{1\}} f_i = f_1 \).

c) If \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) and \((f_i)_{i \in J} \in C[[\mathcal{M}]]^J \) are Noetherian and \( I \cap J = \emptyset \), then \((f_i)_{i \in I \cup J} \) is Noetherian and \( \sum_{i \in I \cup J} f_i = \sum_{i \in I} f_i + \sum_{i \in J} f_i \).

d) If \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) is a Noetherian family, then for any bijective mapping \( \varphi : J \to I \), the family \((f_{\varphi(j)})_{j \in J} \) is Noetherian, and \( \sum_{j \in J} f_{\varphi(j)} = \sum_{i \in I} f_i \).

e) If \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) is a Noetherian family and \( I = \bigsqcup_{j \in J} I_j \) a decomposition of \( I \) into pairwise disjoint subsets, then \((f_i)_{i \in I} \) is a Noetherian family for each \( j \in J \), \((\sum_{i \in I_j} f_i)_{i \in I_j} \) is a Noetherian family, and \( \sum_{j \in J} \sum_{i \in I_j} f_i = \sum_{i \in I} f_i \).

Proof. All properties are straightforward to prove. For illustration, we will prove (e). Let \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) be a Noetherian family and let \( I = \bigsqcup_{j \in J} I_j \) a partition of \( I \). For each \( m \in \mathcal{M} \) and \( j \in J \), let \( I_{j,m} = \{ i \in I \mid f_i \neq 0 \} \) and \( I_{j,m} = I_j \cap I_{j,m} \), so that

\[
I_{j,m} = \bigsqcup_{j \in J} I_{j,m}.
\]

Now \((f_i)_{i \in I_j} \) is a Noetherian family for all \( j \in J \), since \( \bigcup_{i \in I_j} \supp(f_i) \subseteq \bigcup_{i \in I_j} \supp(f_i) \) and \( I_{j,m} \subseteq I_{j,m} \) is finite for all \( m \in \mathcal{M} \). Furthermore, \( \bigcup_{j \in J} \supp(\sum_{i \in I_j} f_i) \subseteq \bigcup_{j \in J} \bigcup_{i \in I_j} \supp(f_i) = \bigcup_{i \in I} \supp(f_i) \) and for all \( m \in \mathcal{M} \), the set \( \{ j \in J \mid (\sum_{i \in I_j} f_i)_{m} \neq 0 \} \subseteq \{ j \in J \mid I_{j,m} \neq \emptyset \} \) is finite, because of (3). Hence, the family \((\sum_{i \in I_j} f_i)_{j \in J} \) is Noetherian and for all \( m \in \mathcal{M} \), we have

\[
\left( \sum_{j \in J} \sum_{i \in I_j} f_i \right)_{m} = \sum_{j \in J} \sum_{i \in I_{j,m}} f_i_{m} = \sum_{i \in I_{m}} f_i_{m} = \left( \sum_{i \in I} f_i \right)_{m}.
\]

This proves (e). \( \square \)

Remark 7. Given two monomial sets \( \mathcal{M} \) and \( \mathcal{N} \), it is often convenient to identify \( C[[\mathcal{M}]] \times C[[\mathcal{N}]] = C[[\mathcal{M} \oplus \mathcal{N}]] \) with \( C[[\mathcal{M} \cup \mathcal{N}]] \) via the natural isomorphism

\[
C[[\mathcal{M} \cup \mathcal{N}]] \to C[[\mathcal{M}]] \times C[[\mathcal{N}]]
\]

\[
f \mapsto (\sum_{m \in \mathcal{M}} f_{m} m, \sum_{n \in \mathcal{N}} f_{n} n).
\]

In particular multivariate operators \( \Phi : C[[\mathcal{M}]] \times \cdots \times C[[\mathcal{M}_m]] \to C[[\mathcal{N}]] \times \cdots \times C[[\mathcal{N}_n]] \) may actually be regarded as a univariate operators \( \Phi : C[[\mathcal{M}_1 \cdots \mathcal{M}_m]] \to C[[\mathcal{N}_1 \cdots \mathcal{N}_n]] \). Similarly, given a monomial set \( \mathcal{M} \), the Noetherian families \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) may be identified with series in \( C[[I \times \mathcal{M}]] \), where \( I \times \mathcal{M} \) is strictly ordered by \( (i, m) \prec (j, n) \Leftrightarrow m < n \). We may thus view an operator \( \Phi : C[[I \times \mathcal{M}]] \to C[[\mathcal{M}]] \) as an operator “in infinitely many variables”, which assigns to each Noetherian family \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) a series in \( C[[\mathcal{M}]] \).

3.2 Algebras of Noetherian series

Assume now that \( C \) is a (not necessarily commutative) ring, and \( \mathcal{M} \) a (not necessarily commutative) monomial monoid. Then we may naturally see \( C \) and \( \mathcal{M} \) as subsets of \( C[[\mathcal{M}]] \) via \( c \mapsto c \cdot 1 \) resp. \( m \mapsto 1 \cdot m \). Given \( f \) and \( g \) in \( C[[\mathcal{M}]] \), we define their product by

\[
f g = \sum_{(m, n) \in \text{supp} f \times \text{supp} g} f_{m} g_{n} m n.
\]
The right hand side is well defined by propositions 4(e) and 4(b). Higman [Hig52] first observed that $C[[\mathfrak{M}]]$ is a ring for this product. Actually, it is even a strong ring, because the product is compatible with the infinite summation structure on $C[[\mathfrak{M}]]$ in the following way:

**Proposition 8.** For all Noetherian families $(f_i)_{i \in I} \in C[[\mathfrak{M}]]^I$ and $(g_j)_{j \in J} \in C[[\mathfrak{M}]]^J$, the family $(f_i g_j)_{(i,j) \in I \times J}$ is also Noetherian, and

$$\sum_{(i,j) \in I \times J} f_i g_j = \left( \sum_{i \in I} f_i \right) \left( \sum_{j \in J} g_j \right).$$

**Proof.** First of all,

$$\bigcup_{(i,j) \in I \times J} \text{supp } f_i g_j \subseteq \bigcup_{(i,j) \in I \times J} \left( \text{supp } f_i \right) \left( \text{supp } g_j \right) = \left( \bigcup_{i \in I} \text{supp } f_i \right) \left( \bigcup_{j \in J} \text{supp } g_j \right)$$

is Noetherian. Given $m \in \mathfrak{M}$, the set of couples $(v, w) \in \left( \bigcup_{i \in I} \text{supp } f_i \right) \times \left( \bigcup_{j \in J} \text{supp } g_j \right)$ with $vw = m$ forms a finite antichain; let $(v_1, w_1), \ldots, (v_n, w_n)$ denote those couples. Then

$$\{(i, j) \in I \times J | (f_i g_j)_m \neq 0\} \subseteq \bigcup_{k=1}^n \{(i, j) \in I \times J | f_{i_k} g_{j_k} \neq 0 \wedge g_{j_k} \neq 0\}$$

is finite, whence $(f_i g_j)_{(i,j) \in I \times J}$ is a Noetherian family. Given $m \in \mathfrak{M}$, we also have

$$\left( \sum_{(i,j) \in I \times J} f_i g_j \right)_m = \sum_{(i,j) \in I \times J} \sum_{k=1}^n f_{i_k} g_{j_k} = \sum_{k=1}^n \left( \sum_{i \in I} f_i \right)_{v_k} \left( \sum_{j \in J} g_j \right)_{w_k} = \left( \sum_{i \in I} f_i \right) \left( \sum_{j \in J} g_j \right)_m,$$

with $(v_1, w_1), \ldots, (v_n, w_n)$ as above. $\square$

**Remark 9.** Also, if $(f_i)_{i \in I} \in C[[\mathfrak{M}]]^I$ is a Noetherian family, then so is $(\lambda_i f_i)_{i \in I}$, for each family $(\lambda_i)_{i \in I} \in C^I$ of scalars.

### 3.3 Extension by strong linearity

Let $C$ be a ring and let $\mathfrak{M}, \mathfrak{N}$ be monomial sets. In all what follows, we understand that $C$ operates on the left on $C$-modules and $C$-algebras. A linear mapping $L: C[[\mathfrak{M}]] \to C[[\mathfrak{N}]]$ is said to be strongly additive, if for all Noetherian families $(f_i)_{i \in I} \in C[[\mathfrak{M}]]^I$, the family $(L(f_i))_{i \in I} \in C[[\mathfrak{N}]]^I$ is also Noetherian and

$$L \left( \sum_{i \in I} f_i \right) = \sum_{i \in I} L(f_i).$$

Notice that this condition implies that $L$ is strongly linear, i.e. $L \left( \sum_{i \in I} \lambda_i f_i \right) = \sum_{i \in I} \lambda_i L(f_i)$, for every Noetherian family $(f_i)_{i \in I} \in C[[\mathfrak{M}]]^I$ and every family $(\lambda_i)_{i \in I} \in C^I$ of scalars. Notice also that the composition of two strongly linear mappings is again strongly linear.
A mapping \( \varphi : \mathcal{M} \to C[[\mathfrak{M}]] \) is said to be Noetherian, if \( (\varphi(m))_{m \in \mathcal{G}} \) is a Noetherian family for every Noetherian subset \( \mathcal{G} \) of \( \mathcal{M} \).

**Proposition 10.** Let \( C[[\mathfrak{M}]] \) and \( C[[\mathfrak{N}]] \) be \( C \)-modules of Noetherian series. Then any Noetherian mapping \( \varphi : \mathcal{M} \to C[[\mathfrak{N}]] \) extends to a unique strongly linear mapping \( \tilde{\varphi} : C[[\mathfrak{M}]] \to C[[\mathfrak{N}]] \).

**Proof.** Let \( f \in C[[\mathfrak{M}]] \). By definition, \( (\varphi(m))_{m \in \text{supp} f} \) is a Noetherian family, and so is \( (f_m \varphi(m))_{m \in \text{supp} f} \). We will prove that

\[
\tilde{\varphi} : C[[\mathfrak{M}]] \to C[[\mathfrak{N}]]
\]

\[
f \mapsto \sum_{m \in \text{supp} f} f_m \varphi(m)
\]

is the unique strongly linear mapping which coincides with \( \varphi \) on \( \mathcal{M} \).

Given \( \lambda \in C \) and \( f \in C[[\mathfrak{M}]] \) we clearly have \( \varphi(\lambda f) = \lambda \varphi(f) \). Now let \( (f_i)_{i \in I} \in C[[\mathfrak{M}]]^I \) be a Noetherian family and denote \( \mathcal{G} = \bigcup_{i \in I} \text{supp} f_i \). We claim that \( (f_{i,m} \varphi(m))_{(i,m) \in I \times \mathcal{G}} \) is a Noetherian family. First of all,

\[
\bigcup_{(i,m) \in I \times \mathcal{G}} \text{supp} f_{i,m} \varphi(m) \subseteq \bigcup_{m \in \mathcal{G}} \text{supp} \varphi(m)
\]

is Noetherian. Seconded, given \( n \in \mathfrak{N} \), the set \( \{ m \in \mathcal{G} | \varphi(m)_n \neq 0 \} \) is finite, since \( (\varphi(m))_{m \in \mathcal{G}} \) is a Noetherian family. Finally, for each \( m \in \mathcal{G} \) with \( \varphi(m)_n \neq 0 \), the set \( \{ i \in I | f_{i,m} \neq 0 \} \) is also finite, since \( (f_i)_{i \in I} \) is a Noetherian family. Hence, the set \( \{(i,m) \in I \times \mathcal{G} | f_{i,m} \varphi(m)_n \neq 0 \} \) is finite, which proves our claim. Now our claim, together with proposition 6(d) proves that \( (\varphi^\mathcal{G})(f_i)_{i \in I} = \left( \sum_{m \in \mathcal{G}} f_{i,m} \varphi(m) \right)_{i \in I} \) is a Noetherian family and

\[
\tilde{\varphi}(f) = \sum_{i \in I} \left( \sum_{m \in \mathcal{G}} f_{i,m} \varphi(m) \right) = \sum_{i \in I, (i,m) \in \mathcal{G}} f_{i,m} \varphi(m) = \sum_{m \in \mathcal{G}} \left( \sum_{i \in I} f_{i,m} \varphi(m) \right) = \tilde{\varphi} \left( \sum_{i \in I} f_i \right).
\]

This establishes the strong linearity of \( \varphi \).

In order to see that \( \varphi \) is unique with the desired properties, it suffices to observe that for each \( f \in C[[\mathfrak{M}]] \), we must have \( \varphi(f_m) = f_m \varphi(m) \) by linearity and \( \varphi(f) = \sum_{m \in \text{supp} f} f_m \varphi(m) \) by strong linearity. \( \square \)

Actually, the above proposition generalizes to the “strongly multilinear” case. If \( \mathcal{M}_1, \ldots, \mathcal{M}_n \) and \( \mathfrak{M} \) are monomial sets, then we call a multilinear mapping

\[
M : C[[\mathfrak{M}_1]] \times \cdots \times C[[\mathfrak{M}_n]] \to C[[\mathfrak{M}]]
\]

**strongly multilinear** (or **strongly multi-additive**), if for all Noetherian families \( (f_{1,i_1})_{i_1 \in I_1} \in C[[\mathfrak{M}_1]]^{I_1}, \ldots, (f_{n,i_n})_{i_n \in I_n} \in C[[\mathfrak{M}_n]]^{I_n} \), the family \( M(f_{1,i_1,\ldots,i_n})_{(i_1,\ldots,i_n) \in I_1 \times \cdots \times I_n} \) is also Noetherian and

\[
M \left( \sum_{i_1 \in I_1} f_{1,i_1}, \ldots, \sum_{i_n \in I_n} f_{n,i_n} \right) = \sum_{(i_1,\ldots,i_n) \in I_1 \times \cdots \times I_n} M(f_{1,i_1,\ldots,i_n}).
\]

In particular, if \( \mathcal{M} \) is a monomial monoid, then the multiplication on \( C[[\mathfrak{M}]] \) is strongly bilinear, by proposition 8. Also, compositions

\[
N \circ \prod_{i=1}^m M_i : \prod_{i=1}^m \prod_{j=1}^{n_i} C[[\mathfrak{M}_{i,j}]] \to C[[\mathfrak{M}]];
\]

\[
((f_{i,j})_{1 \leq i \leq m_1}) \cdots ((f_{i,j})_{1 \leq i \leq m_n}) \mapsto N(M_1(f_{1,1},\ldots,f_{1,n_1}),\ldots,M_m(f_{m,1},\ldots,f_{m,n_m}))
\]
of strongly multilinear mappings $N: C[[M_1]] \times \cdots \times C[[M_m]] \to C[[N]]$ and $M_i: C[[M_{i,1}]] \times \cdots \times C[[M_{i,n_i}]] \to C[[N_i]]$ for $i \in \{1, \ldots, m\}$ are strongly multilinear.

Recall that a mapping $\varphi: M_1 \times \cdots \times M_n \to C[[N]]$ is Noetherian, if $(\varphi(m_1, \ldots, m_n))(m_1, \ldots, m_n) \subseteq S$ is a Noetherian family for every Noetherian subset $S$ of $M_1 \times \cdots \times M_n$. The following proposition is proved in a similar way as proposition 10:

**Proposition 11.** Let $C[[M_1]], \ldots, C[[M_n]]$ and $C[[N]]$ be $C$-modules of Noetherian series. Then any Noetherian mapping $\varphi: M_1 \times \cdots \times M_n \to C[[N]]$ extends to a unique strongly multilinear mapping $\hat{\varphi}: C[[M_1]] \times \cdots \times C[[M_n]] \to C[[N]]$. □

**Remark 12.** In a similar way as we identified $C[[M_1]] \otimes C[[N]]$ with $C[[M \times N]]$ in remark 7, we may see $C[[M \times N]]$ as the strong tensor product of $C[[M]]$ and $C[[N]]$. We have a naturally strongly bilinear mapping $P: C[[M]] \times C[[N]] \to C[[M \times N]]$: $(f, g) \mapsto \sum_{(m, n) \in \text{supp } f \times \text{supp } g} f_m g_n (m, n)$. Furthermore, for any strongly bilinear mapping $B: C[[M]] \times C[[N]] \to C[[N]]$, there exists a unique strongly linear mapping $L: C[[M \times N]] \to C[[N]]$, such that $B = L \circ P$.

### 3.4 Applications of strong linearity

**Corollary 13.** Let $M$ and $N$ be monomial monoids and let $\varphi: M \to C[[N]]$ be a Noetherian mapping which preserves multiplication. Then $\hat{\varphi}$ preserves multiplication.

**Proof.** The mappings $(f, g) \mapsto \varphi(f \cdot g)$ and $(f, g) \mapsto \varphi(f) \cdot \varphi(g)$ are both strongly bilinear mappings from $C[[M]] \times C[[N]]$ into $C[[N]]$, which coincide on $M^2$. The result now follows from the uniqueness of strongly bilinear extensions in proposition 11. □

**Corollary 14.** Let $M$ be a monomial monoid and $\varphi: M \to C[[N]]$ a Noetherian mapping, such that $\varphi(mn) = \varphi(m) n + m \varphi(n)$ for all $m, n \in M$. Then $\hat{\varphi}$ is a (strong) derivation on $C[[N]]$.

**Proof.** The mappings $(f, g) \mapsto \varphi(f \cdot g)$ and $(f, g) \mapsto \varphi(f) g + f \varphi(g)$ are both strongly bilinear mappings from $C[[M]] \times C[[N]]$ into $C[[N]]$, which coincide on $M^2$. The result again follows from the uniqueness of strongly bilinear extensions in proposition 11. □

**Corollary 15.** Let $\varphi: M \to C[[N]]$ and $\psi: N \to C[[M]]$ be two Noetherian mappings. Then

$$\hat{\psi} \circ \varphi = \hat{\psi} \circ \varphi.$$

**Proof.** This still follows from the uniqueness of extensions by strong linearity, since $\hat{\psi} \circ \varphi$ and $\hat{\psi} \circ \varphi$ coincide on $M$. □

Assume that $M$ is a monomial monoid. We call a series $f \in C[[M]]$ infinitesimal, if $m < 1$ for all $m \in \text{supp } f$. Then extension by strong linearity may in particular be used to define the composition $g \circ (f_1, \ldots, f_k)$ of a multivariate power series $g \in C[[z_1, \ldots, z_k]] = C[[z_1^n \cdots z_k^n]]$ with infinitesimal series $f_1, \ldots, f_k \in C[[M]]$. Indeed, if $\varphi: M \to C[[N]]$ is the multiplicative mapping which sends each $z_1^{n_1} \cdots z_k^{n_k}$ to $f_1^{n_1} \cdots f_k^{n_k}$, then we define $g \circ (f_1, \ldots, f_k) = \varphi(g)$. Then corollaries 13 and 15 yield the following result:

**Corollary 16.** Let $f_1, \ldots, f_k$ be infinitesimal Noetherian series in $C[[M]]$. Then

a) $(gh) \circ (f_1, \ldots, f_k) = g \circ (f_1, \ldots, f_k) h \circ (f_1, \ldots, f_k)$, for $g, h \in C[[z_1, \ldots, z_k]]$. 

b) \((h \circ (g_1, \ldots, g_l)) \circ (f_1, \ldots, f_k) = h \circ (g_1 \circ (f_1, \ldots, f_k), \ldots, g_l \circ (f_1, \ldots, f_k))\), for \(h \in C[[z_1, \ldots, z_l]]\) and infinitesimal \(g_1, \ldots, g_l \in C[[z_1, \ldots, z_l]]\).

\[\square\]

4 The topological implicit function theorem

4.1 Truncation of Noetherian series

Let \(M\) be a monomial set and \(f \in C[[M]]\). Given a subset \(S \subseteq M\), we define the restriction \(f|_S \in C[[S]] \subseteq C[[M]]\) of \(f\) to \(S\) by

\[f|_S = \sum_{m \in S \cap \text{supp} f} f_m m.\]

Given two series \(f, g \in C[[M]]\), we say that \(f\) is a truncation of \(g\) (and we write \(f \trianglelefteq g\)), if there exists an initial segment \(I\) of \(\text{supp} g\), such that \(f = g|_I\). Thus \(\trianglelefteq\) is an ordering on \(C[[M]]\).

Let \((f_i)_{i \in I} \in C[[M]]^I\) be a non-empty family of series. A common truncation of the \(f_i\) is a series \(g\), such that \(g \trianglelefteq f_i\) for all \(i \in I\). A greatest common truncation of the \(f_i\) is a common truncation, which is greatest for \(\trianglelefteq\). Such a greatest truncation actually always exists and we denote it by \(\bigtriangleup_{i \in I} f_i\):

**Proposition 17.** Any non-empty family \((f_i)_{i \in I} \in C[[M]]\) admits a greatest common truncation.

**Proof.** Fix some \(j \in I\) and consider the set \(I\) of initial segments \(J\) of \(\text{supp} f_j\), such that \(f_j \trianglelefteq f_i\) for all \(i \in I\). We observe that arbitrary unions of initial segments of a given ordering are again initial segments. Hence \(\bigtriangleup_{J \in I} J\) is an initial segment of each \(\text{supp} f_i\). Furthermore, for each \(i \in I\) and \(m \in \bigtriangleup_{J \in I} J\), there exists an \(I \in I\) with \(f_j \trianglelefteq m = f_j \trianglelefteq f_i\).

Hence \(f_j \trianglelefteq f_i\) is a common truncation of the \(f_i\). It is also greatest for \(\trianglelefteq\), since any common truncation is of the form \(f_j \trianglelefteq f_i\) for some initial segment \(J \in I\) of \(\bigtriangleup_{J \in I} J\) with \(f_j \trianglelefteq f_i\).

Let \((f_i)_{i \in I} \in C[[M]]^I\) again be a family of series. A common extension of the \(f_i\) is a series \(g\), such that \(f_i \trianglelefteq g\) for all \(i \in I\). A least common extension of the \(f_i\) is a common extension, which is least for \(\trianglelefteq\). If such a least common extension exists, then we denote it by \(\bigtriangledown_{i \in I} f_i\).

Now consider a directed index set \(I\). In other words, we have an ordering on \(I\), such that for any \(i, j \in I\), there exist a \(k \in I\) with \(i \leq k \leq j\). Let \((f_i)_{i \in I}\) be a \(\trianglelefteq\)-increasing family of series in \(C[[M]]\), i.e. \(f_i \trianglelefteq f_j\) whenever \(i \leq j\). If \(M\) is Noetherian or totally ordered, then there exists a least common extension of the \(f_i\):

**Proposition 18.** Assume that \(M\) is Noetherian or totally ordered. Then any directed \(\trianglelefteq\)-increasing family \((f_i)_{i \in I}\) of series in \(C[[M]]\) admits a unique least common extension \(\bigtriangledown_{i \in I} f_i\) and supp \(\bigtriangledown_{i \in I} f_i = \bigcup_{i \in I} \text{supp} f_i\).

**Proof.** Let \(S = \bigcup_{i \in I} \text{supp} f_i\). We claim that \(S\) is Noetherian. This is clear if \(M\) is Noetherian. Assume that \(M\) is totally ordered and that \(m_1 \leq m_2 \leq \cdots\) is an infinite sequence of monomials in \(S\). Since \(I\) is directed and supp \(f_i \subset \text{supp} f_j\) whenever \(i \leq j\), there exist \(i_1 \leq i_2 \leq \cdots\) with \(m_k \in \text{supp} f_{i_k}\) for each \(k\). But we also have \(f_{i_1} \trianglelefteq f_{i_k}\) for each \(k\), so that \(m_1, m_2, \ldots \in \text{supp} f_{i_1}\). Since supp \(f_{i_1}\) is Noetherian, the sequence \(m_1, m_2, \ldots\) therefore stabilizes.
Proposition 19. If \( m \in \mathcal{S} \), we claim that the coefficient \( g_m = f_{i,m} \) is independent of the choice of \( i \in I \), under the condition that \( m \in \text{supp} f_i \). Indeed, let \( i, j \in I \) be such that \( m \in \text{supp} f_i \) and \( m \in \text{supp} f_j \), then there exists a \( k \in I \) with \( i \leq k \) and \( j \leq k \). Hence, \( f_i \sqsubseteq f_k \) and \( f_j \sqsubseteq f_k \), so that \( f_{i,m} = f_{k,m} = f_{j,m} \). Now the series \( g = \sum_{m \in \mathcal{S}} g_m m \) is the least common extension of the \( f_i \).

\[ \square \]

4.2 Stationary limits

Let \( I \) be a directed index set and \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) a family of series. We call \( g \in C[[\mathcal{M}]] \) a pseudo-limit of the \( f_i \), if for each final segment \( \mathfrak{F} \) of \( \mathcal{M} \) and for all \( i \in I \), we have

\[ (\forall j \geq i : \text{supp} (f_j - f_i) \subseteq \mathfrak{F} \Rightarrow (\text{supp} (g - f_i) \subseteq \mathfrak{F})). \]

Equivalently, we may require that for each initial segment \( \mathfrak{J} \) of \( \mathcal{M} \) and for each \( i \in I \), we have

\[ (\forall j \geq i : f_{j|\mathfrak{J}} = f_{i|\mathfrak{J}} \Rightarrow (g|_{\mathfrak{J}} = f_{i|\mathfrak{J}})). \]

Assume from now on that \( \mathcal{M} \) is either Noetherian or totally ordered. Below, we will show that the stationary limit of the \( f_i \), which is defined by

\[ \text{stat lim} f_i = \bigtriangledown \bigtriangleup_{i \in I} f_j \]

is in particular a pseudo-limit. We first prove some useful properties of \( \bigtriangledown \) and \( \bigtriangleup \).

**Proposition 19.** Let \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) be a family of series and let \( \mathfrak{I} \) be an initial segment of \( \mathcal{M} \).

a) If \( I \neq \emptyset \), then

\[ \bigtriangleup_{i \in I} f_{i|\mathfrak{I}} = \left( \bigtriangleup_{i \in I} f_i \right) | \mathfrak{I} \cdot \]

b) If \((f_i)_{i \in I} \) is directed and \( \sqsubseteq \)-increasing, then

\[ \bigtriangledown_{i \in I} f_{i|\mathfrak{I}} = \left( \bigtriangledown_{i \in I} f_i \right) | \mathfrak{I} \cdot \]

**Proof.** We first observe that for all \( f, g \in C[[\mathcal{M}]] \) we have \( f \sqsubseteq g \Rightarrow f_{i|\mathfrak{I}} \sqsubseteq g_{i|\mathfrak{I}} \). In particular, this ensures that \( \bigtriangledown_{i \in I} f_{i|\mathfrak{I}} \) exists in (b).

Now assume that \( I \neq \emptyset \) and let \( g = \Delta_{i \in I} f_i \). Then \( g \sqsubseteq f_i \), whence \( g_{i|\mathfrak{J}} \sqsubseteq f_{i|\mathfrak{J}} \), for all \( i \in I \).

This shows that \( g_{i|\mathfrak{J}} \) is a common truncation of the \( f_{i|\mathfrak{J}} \). Inversely, assume that \( h \in C[[\mathfrak{J}]] \) is such that \( h \sqsubseteq f_{i|\mathfrak{J}} \) for all \( i \in I \). Then also \( h \sqsubseteq f_i \) for all \( i \in I \), so that \( h \sqsubseteq g \). Hence \( h = h_{i|\mathfrak{J}} \sqsubseteq g_{i|\mathfrak{J}} \).

This shows that \( g_{i|\mathfrak{J}} \) is the greatest common truncation of the \( f_{i|\mathfrak{J}} \).

Assume now that \((f_i)_{i \in I} \) is directed and \( \sqsubseteq \)-increasing and let \( g = \bigtriangledown_{i \in I} f_i \). Then \( f_i \sqsubseteq g \), whence \( f_{i|\mathfrak{J}} \sqsubseteq g_{i|\mathfrak{J}} \), for all \( i \in I \). Consequently, \( g_{i|\mathfrak{J}} \) is a common extension of the \( f_{i|\mathfrak{J}} \).

Furthermore, its support \( \text{supp} g_{i|\mathfrak{J}} = (\text{supp} g) \cap \mathfrak{J} = (\bigcup_{i \in I} \text{supp} f_i) \cap \mathfrak{J} = \bigcup_{i \in I} \text{supp} f_i \cap \mathfrak{J} = \bigcup_{i \in I} \text{supp} f_{i|\mathfrak{J}} \) is the same as the support of the least common extension of the \( f_{i|\mathfrak{J}} \). Hence \( g_{i|\mathfrak{J}} = \bigtriangledown_{i \in I} f_{i|\mathfrak{J}} \).

\[ \square \]

**Proposition 20.** Let \((f_i)_{i \in I} \in C[[\mathcal{M}]]^I \) be a directed family and \( i \in I \). Then

\[ \bigtriangledown_{j \in I} \bigtriangleup_{k \geq j} f_k = \bigtriangledown_{j \geq i} \bigtriangleup_{k \geq j} f_k. \]
Proof. Since \( I \supseteq \{ j \in I \mid j \geq i \} \), we have \( \bigwedge_{j \in I} \bigwedge_{k \geq j} f_k \supseteq \bigwedge_{j \geq i} \bigwedge_{k \geq j} f_k \). On the other hand, given \( m \in \text{supp} \bigwedge_{j \in I} \bigwedge_{k \geq j} f_k \), we have \( m \in \bigwedge_{k \geq j} f_k \) for some \( j \in I \). Choosing \( l \in I \) with \( l \geq i \) and \( l \geq j \), we then have \( m \in \bigwedge_{k \geq l} f_k \supseteq \bigwedge_{k \geq j} f_k \) and \( m \in \bigcup_{m \geq i} \text{supp} \bigwedge_{k \geq m} f_k = \text{supp} \bigwedge_{m \geq i} \bigwedge_{k \geq m} f_k \).  

Proposition 21. For any directed family \( (f_i)_{i \in I} \subseteq C[[\mathcal{M}]] \), its stationary limit is a pseudo-limit.

Proof. Let \( J \) be an initial segment of \( \mathcal{M} \) and let \( i \in I \) be such that \( f_{j|\mathcal{M}} = f_{i|\mathcal{M}} \) for all \( j \geq i \). Then proposition 19 implies that

\[
\left( \bigwedge_{j \geq i} \bigwedge_{k \geq j} f_k \right) |_{\mathcal{M}} = \bigwedge_{j \geq i} \bigwedge_{k \geq j} f_{k|\mathcal{M}} = \bigwedge_{j \geq i} \bigwedge_{k \geq j} f_{i|\mathcal{M}} = f_{i|\mathcal{M}}.
\]

Hence \( \text{stat lim}_{j \in I} f_j |_{\mathcal{M}} = f_{i|\mathcal{M}} \), by proposition 20. \( \square \)

Given \( f \) and \( g \) in \( C[[\mathcal{M}]] \), we will write \( f \prec g \), if for all \( m \in \text{supp} f \), there exists an \( n \in \text{supp} g \) with \( m \prec n \). The following properties of \( \prec \) will be used frequently in the next section:

Proposition 22. Let \( f, g, h \in C[[\mathcal{M}]] \). Then

a) \( f \prec f \) if and only if \( f = 0 \).

b) \( f \prec g \land g \prec h \Rightarrow f \prec h \).

c) \( f \prec h \land g \prec h \Rightarrow f + g \prec h \).

d) If \( (f_i)_{i \in I} \subseteq C[[\mathcal{M}]] \) now stands for a directed family, then

\[
\left( \forall i \in I : f_i \prec g \right) \Rightarrow \left( (\text{stat lim}_{i \in I} f_i) - g \prec h \right).
\]

Proof. The first three properties are trivial. Consider the final segment

\[
\mathcal{F} = \{ m \in \mathcal{M} \mid \forall \vartheta > m, \text{ for some } \preceq\text{-maximal element } \vartheta \text{ in supp } h \}.
\]

Then our hypothesis means that \( \text{supp} (f_i - g) \subseteq \mathcal{F} \) for all \( i \). Now \( \text{supp} (\text{stat lim}_{i \in I} f_i) - g \subseteq \mathcal{F} \), by proposition 21. But this means that \( (\text{stat lim}_{i \in I} f_i) - g \prec h \). \( \square \)

4.3 The implicit function theorem

A final segment \( \mathcal{F} \) of a monomial set \( \mathcal{M} \) is said to be attractive, if for each \( m \in \mathcal{M} \) there exists an \( n \in \mathcal{F} \) with \( m \succ n \). If \( \mathcal{M} \) is totally ordered, then all non-empty final segments are attractive. The intersection of two attractive final segments is again an attractive final segment and arbitrary non-empty unions of attractive final segments are again attractive final segments. In other words, the attractive final subsets \( \mathcal{F} \) of \( \mathcal{M} \) together with the empty set are the open sets of a topology on \( \mathcal{M} \).

Now let \( C \) be a commutative additive group. The attractive open subsets of \( C[[\mathcal{M}]] \) are the subsets of the form \( f + C[[\mathcal{F}]] \), where \( f \in C[[\mathcal{M}]] \) and where \( \mathcal{F} \) is an attractive final segment of \( \mathcal{M} \). These sets form a basis for the open subsets of the natural or attractive topology on \( C[[\mathcal{M}]] \). We notice that the attractive topology makes \( C[[\mathcal{M}]] \) an additive topological group. Given another monomial set \( \mathcal{N} \), we also notice that the attractive topology on \( C[[\mathcal{M}]] \times C[[\mathcal{N}]] \cong C[[\mathcal{M} \cup \mathcal{N}]] \) (remember remark 7) coincides with the usual product topology on \( C[[\mathcal{M}]] \times C[[\mathcal{N}]] \) (if \( C[[\mathcal{M}]] \) and \( C[[\mathcal{N}]] \) are given the attractive topologies).
Consider a mapping $\Phi: C[[\mathcal{M}]] \to C[[\mathcal{M}]]$, where $\mathcal{M} \neq \emptyset$. We call $\Phi$ contracting, if for all $f, g \in C[[\mathcal{M}]]$, we have $\Phi(g) - \Phi(f) \prec g - f$. A contracting mapping is in particular continuous at each point $f \in C[[\mathcal{M}]]$, since for any attractive open neighbourhood $\Phi(f) + C[[\mathcal{F}]]$ of $\Phi(f)$, the set $f + C[[\mathcal{F}]]$ is an open neighbourhood of $f$ with $\Phi(f + C[[\mathcal{F}]]) \subset \Phi(f) + C[[\mathcal{F}]]$.

**Theorem 23.** Assume that $\mathcal{M} \neq \emptyset$ is Noetherian or totally ordered and let $\Phi: C[[\mathcal{M}]] \times C[[\mathcal{M}]] \to C[[\mathcal{M}]]$ be a continuous mapping, such that the mapping $\Phi_g: C[[\mathcal{M}]] \to C[[\mathcal{M}]]$; $f \mapsto \Phi(f, g)$ is contracting for each $g \in C[[\mathcal{M}]]$. Then there exists a unique mapping $\Psi: C[[\mathcal{M}]] \to C[[\mathcal{M}]]$ with $\Psi(g) = \Phi(\Psi(g), g)$ for each $g \in C[[\mathcal{M}]]$, and $\Psi$ is continuous.

**Proof.** Given $g \in C[[\mathcal{M}]]$, consider the transfinite sequence $(f_\alpha)_\alpha$ defined as follows:

$$
\begin{align*}
\alpha+1 & \in C[[\mathcal{M}]] \ (\text{any choice of } f_0 \text{ will do}); \\
\lambda & = \text{stat lim } f_\alpha, \text{ for limit ordinals } \lambda.
\end{align*}
$$

We will show that $(f_\alpha)_\alpha$ converges to a solution of the equation $f = \Phi_g(f)$.

The sequence $f_{\alpha+1} - f_\alpha$ decreases for $\preceq$. Let us prove by (weak) transfinite induction over $\alpha$ that $f_{\alpha+1} - f_\alpha \preceq f_{\beta+1} - f_\beta$ for all ordinals $\beta < \alpha$. This is clear for $\alpha = 0$. Assume that $\alpha = \beta + 1$ is a successor ordinal. Since $\Phi_g$ is contracting, the induction hypothesis then implies that $f_{\alpha+1} - f_\alpha \preceq f_{\beta+1} - f_\beta \preceq f_{\gamma+1} - f_{\gamma}$ for all $\gamma \leq \beta < \alpha$.

If $\alpha$ is a limit ordinal and $\beta < \alpha$, then let us prove by a second (weak) transfinite induction over $\gamma$ that $f_{\gamma} - f_{\beta+1} \preceq f_{\beta+1} - f_\beta$ for all $\beta + 1 < \gamma < \alpha$. This is indeed true for $\gamma = \beta + 2$, by the first induction hypothesis. Assuming that $f_{\gamma} - f_{\beta+1} \preceq f_{\beta+1} - f_\beta$, we also have

$$f_{\gamma+1} - f_{\beta+1} = (f_{\gamma+1} - f_\gamma) + (f_\gamma - f_{\beta+1}) \preceq f_{\beta+1} - f_\beta,$$

again by the first induction hypothesis and proposition 22(c). If $\gamma$ is a limit ordinal, then the second induction hypothesis implies that $f_\delta - f_{\beta+1} \preceq f_{\beta+1} - f_\beta$ for all $\beta < \delta < \gamma$. Hence,

$$f_\gamma - f_{\beta+1} = (\text{stat lim } f_\delta) - f_{\beta+1} = (\text{stat lim } f_\delta) - f_{\beta+1} \preceq f_{\beta+1} - f_\beta,$$

by proposition 22(d).

At this point, we have proved that $f_\gamma - f_{\beta+1} \preceq f_{\beta+1} - f_\beta$ for all $\beta + 1 < \gamma < \alpha$. Now proposition 22(d) implies that

$$f_\alpha - f_{\beta+1} = (\text{stat lim } f_\gamma) - f_{\beta+1} = (\text{stat lim } f_\gamma) - f_{\beta+1} \preceq f_{\beta+1} - f_\beta.$$

In a similar way, one proves that $f_\alpha - f_{\beta+2} \preceq f_{\beta+1} - f_\beta$. Since $\Phi_g$ is contracting, $f_\alpha - f_{\beta+1} \preceq f_{\beta+1} - f_\beta$ also implies that $f_{\alpha+1} - f_{\beta+2} \preceq f_{\beta+1} - f_\beta$. Consequently, $f_{\alpha+1} - f_\alpha = (f_{\alpha+1} - f_{\beta+2}) + (f_{\beta+2} - f_{\beta+1}) + (f_{\beta+1} - f_\alpha) \preceq f_{\beta+1} - f_\beta$, by proposition 22(c).

**Existence and uniqueness.** Having shown that the sequence $f_{\alpha+1} - f_\alpha$ is decreasing for $\preceq$, we now claim that we must have $f_{\alpha+1} - f_\alpha = 0$ for some sufficiently large $\alpha$. Otherwise, each of the sets $\mathfrak{d}(f_{\alpha+1} - f_\alpha)$ of $\preceq$-maximal monomials of $f_{\alpha+1} - f_\alpha$ would be non empty, so that $\mathfrak{d}(f_{\alpha+1} - f_\beta) \cap \mathfrak{d}(f_{\alpha+1} - f_\alpha) \neq \emptyset$ for some $\beta < \alpha$. Indeed, this will happen as soon as the monomials in $\mathfrak{M}$ get exhausted, i.e. for some $\beta < \alpha$ such that the cardinality of $\alpha$ is the one larger than the cardinality of $\mathfrak{M}$. Now let $m \in \mathfrak{d}(f_{\beta+1} - f_\beta) \cap \mathfrak{d}(f_{\alpha+1} - f_\alpha)$. Since $f_{\alpha+1} - f_\alpha \preceq f_{\beta+1} - f_\beta$, there exists an $n \in \text{supp } (f_{\beta+1} - f_\beta)$ with $n > m$. But this contradicts the $\preceq$-maximality of $m$ in $\text{supp } f_{\beta+1} - f_\beta$. This shows our claim and we conclude that the $\Psi(g) \equiv f_\alpha$ with $f_{\alpha+1} - f_\alpha = 0$ satisfies $\Psi(g) = \Phi_g(\Psi(g))$. 
Assume now that two Noetherian series \( f \) and \( f' \) both satisfy \( f = \Psi(f) \) and \( f' = \Psi(g'(f')) \). Then \( f' - f = \Phi_{g}(f') - \Phi_{g}(f) \neq f' - f \), since \( \Phi_{g} \) is contracting. But we can only have \( f' - f \neq f' - f \) if \( f' = f \). This establishes the existence and the uniqueness of the mapping \( \Psi \).

**Continuity.** In order to prove that \( \Psi \) is continuous in any given \( g_{0} \in C[[\mathcal{M}]] \), let \( W = \Psi(g_{0}) + C[[\mathcal{M}]] \) be an attractive open neighbourhood of \( \Psi(g_{0}) \). Then there exists an attractive open subset of \( C[[\mathcal{M}]] \times C[[\mathcal{M}]] \) of the form \( \left( \Psi(g_{0}) + C[[\mathcal{M}]] \right) \times \left( g_{0} + C[[\mathcal{M}]] \right) \), such that \( \Phi(U \times V) \subseteq W \). We claim that \( \Psi(V) \subseteq W \). Indeed, let \( g \in V \). Taking \( f_{0} = \Psi(g_{0}) \) in our sequence above, it suffices to prove that \( f_{\alpha} \in W \) for all \( \alpha \). We prove this by transfinite induction.

For \( \alpha = 0 \) and \( \alpha = 1 \), we are already done. If \( \alpha = \beta + 1 > \gamma \geq 0 \), then \( f_{\alpha} - f_{\beta} \in C[[\mathcal{M}]] \) implies that \( f_{\alpha} - f_{\beta} \in C[[\mathcal{M}]] \), whence \( f_{\alpha} \in W \). If \( \alpha \) is a limit ordinal, then we have seen above that \( f_{\alpha} - f_{\beta + 1} \in C[[\mathcal{M}]] \) for all \( \beta < \alpha \). Taking any such \( \beta \), we also have \( f_{\beta + 1} - f_{\beta} \in C[[\mathcal{M}]] \) by the induction hypothesis, whence again \( f_{\alpha} - f_{\beta + 1} \in C[[\mathcal{M}]] \) and \( f_{\alpha} \in W \). This completes the induction and the proof of the theorem. \( \square \)

**Remark 24.** The theorem still holds for monomial sets \( \mathcal{M} \) without “infinite combs” [PCR93]. Our proof also generalizes to this setting, because it can be shown in this case that the stationary limit of a sequence \( (f_{\alpha})_{\alpha < \beta} \in C[[\mathcal{M}]]^{\beta} \) exists, whenever \( f_{\alpha + 1} - f_{\alpha} \) is strictly decreasing for \( \prec \).

**Remark 25.** Although the above topological implicit function theorem may be very useful to solve certain parameterized functional equations over Noetherian series, one of its major drawbacks is that we needed the very strong Noetherianity assumption on \( \mathcal{M} \) in the partial context. Even the slightly weaker condition about the absence of infinite combs is usually not satisfied. The functional equation

\[
    f(z_{1}, z_{2}) = 1 + (z_{1} + z_{2}) f\left(\sqrt{z_{1}}, \sqrt{z_{2}}\right)
\]

with \( \mathcal{M} = \{ z_{1}^{\alpha_{1}} z_{2}^{\alpha_{2}} | \alpha_{1}, \alpha_{2} \in \mathbb{Q}^{\geq 0} \land \alpha_{1} + \alpha_{2} < 2 \} \) is an example which shows that there is not much hope for a stronger implicit function theorem in the same spirit. Indeed, the natural “solution” to this equation, which is obtained by recursively replacing the left hand side by the right hand side in the equation, does not have a Noetherian support.

**Remark 26.** Another drawback of theorem 23, is that it does not provide us with any additional information about the solutions. The solutions may even be quite pathological: consider the monomial group \( x^{R} \) with \( x^{\alpha} \preceq x^{\beta} \iff \alpha \preceq \beta \). Given \( f \in \mathbb{R}[[x^{R}]] \), we denote \( f^{\uparrow} = \sum_{\alpha > 0} f_{\alpha} x^{\alpha} \). We define a linear (but not strongly linear) operator \( L: \mathbb{R}[[x^{R}]] \to \mathbb{R}[[x^{R}]] \) by

\[
    L(f(x)) = f^{\uparrow}(\sqrt{x}) + f^{\uparrow}(1/\sqrt{x}), \text{ if supp } f \text{ is finite;}
    L(f(x)) = f^{\uparrow}(\sqrt{x}), \text{ otherwise.}
\]

Then it is easily verified that \( L \) is contracting (whence continuous) on \( \mathbb{R}[[x^{R}]] \). The equation

\[
    f(x) = x + L(f(x))
\]

will therefore admit a unique solution, which happens to be \( f(x) = x + \sqrt{x} + \sqrt[3]{x} + \ldots \). However, we do not have \( f(x) = x + L(x) + L(L(x)) + \ldots \).
5. Noetherian operators and combinatorial representations

5.1 Noetherian operators

Let $\mathcal{M}$ and $\mathcal{N}$ be sets of monomials. A \textit{Noetherian operator} is a mapping $\Phi: \mathbb{C}[[\mathcal{M}]] \rightarrow \mathbb{C}[[\mathcal{N}]]$, such that there exists a family $(M_i)_{i \in I}$ of strongly multilinear mappings $M_i: \mathbb{C}[[\mathcal{M}]]^{\{i\}} \rightarrow \mathbb{C}[[\mathcal{N}]]$ with

$$\Phi \left( \sum_{k \in K} f_k \right) = \sum_{i \in I} \sum_{k_1, \ldots, k_{|i|} \in K} M_i(f_{k_1}, \ldots, f_{k_{|i|}}),$$

for all Noetherian families $(f_k)_{k \in K} \in \mathbb{C}[[\mathcal{M}]]^K$. In particular, this assumes that the family of summands $M_i(f_{k_1}, \ldots, f_{k_{|i|}})$ is Noetherian. We will call $(M_i)_{i \in I}$ a \textit{multilinear decomposition} of $\Phi$. The number $|i| \in \mathbb{N}$ is the \textit{arity} of $M_i$.

By regrouping the $M_i$ of the same arity, it actually suffices to consider the case when $I = \mathbb{N}$ and there is exactly one $M_i$ for each arity $i \in \mathbb{N}$. In this case, we may write $\Phi = \Phi_0 + \Phi_1 + \ldots$, with $\Phi_i(f) = M_i(f, \ldots, f)$ for all $f$ and $i$. In section 5.4, we will see that this representation is unique, under the assumption that $C \supseteq \mathbb{Q}$ and that the $M_i$ are symmetric (we may always take the $M_i$ to be symmetric if $C \supseteq \mathbb{Q}$). However, for the purpose of combinatorial representations in the next section, it is natural to consider more general multilinear decompositions. Notice also that the space of Noetherian operators from $C[[\mathcal{M}]] \rightarrow C[[\mathcal{N}]]$ has a natural strong group structure.

\textbf{Remark 27.} The formula (5) should hold in particular for families that consist of only one element. In other words, we should have

$$\Phi(f) = \sum_{i \in I} M_i(f, \ldots, f),$$

for all $f \in C[[\mathcal{M}]]$. However, the more complicated assumption (5) is essential, as you will notice in example 31 below.

\textbf{Remark 28.} In view of remark 7 the present definition of Noetherian operators also provides a definition of multivariate Noetherian operators.

\textbf{Example 29.}

- Each constant mapping $\Phi: C[[\mathcal{M}]] \rightarrow C[[\mathcal{N}]]$: $f \mapsto c$ is a Noetherian operator.
- Any strongly linear or strongly multilinear operator $L$ resp. $M$ is a Noetherian operator.
- Addition $+: C[[\mathcal{M}]]^2 \rightarrow C[[\mathcal{N}]]$: $(f, g) \mapsto f + g$ is a Noetherian operator.
- If $\mathcal{M}$ is a monomial monoid, then multiplication on $C[[\mathcal{M}]]$ is a Noetherian operator.

\textbf{Example 30.} Let $\Phi, \Psi: C[[\mathcal{M}]] \rightarrow C[[\mathcal{N}]]$ be Noetherian operators.

- $\Phi + \Psi: f \mapsto \Phi(f) + \Psi(f)$ is a Noetherian operator.
- If $\mathcal{M}$ is a monomial monoid, then $\Phi \Psi: f \mapsto \Phi(f) \Psi(f)$ is a Noetherian operator.
Example 31. Let $\Phi: C[[\mathfrak{M}]] \to C[[\mathfrak{M}]]$ and $\Psi: C[[\mathfrak{M}]] \to C[[\mathfrak{M}]]$ be two Noetherian operators. Then we claim that $\Psi \circ \Phi$ is also a Noetherian operator. Indeed, let $(M_i)_{i \in I}$ resp. $(N_j)_{j \in J}$ be multilinear decompositions of $\Phi$ and $\Psi$. Then for each Noetherian family $(f_k)_{k \in K} \in C[[\mathfrak{M}]]^K$ we have

$$\Psi \circ \Phi \left( \sum_{k \in K} f_k \right) = \Psi \left( \sum_{i \in I} M_i(f_{k_1, \ldots, k_{|i|}}) \right) = \sum_{j \in J} N_j(M_{i_{|j|}}(f_{k_{|j|,1}, \ldots, f_{k_{|j|,|i_{|j|}}}}), \ldots, M_{i_j}(f_{k_{|j|,1}, \ldots, f_{k_{|j|,|i_{|j|}}}})).$$

This establishes our claim, since the operators $N_j \circ \prod_{i=1}^{|j|} M_i$ are strongly multilinear. Notice that example 30 may be looked at as a combination of the present example and the last two cases in example 29.

One obtains interesting subclasses of Noetherian operators by restricting the strongly multilinear mappings involved in the multilinear decompositions to be of a certain type. More precisely, let $\mathfrak{M}$ be a monomial monoid and let $\mathcal{M}$ be a set of strongly multilinear mappings $M: C[[\mathfrak{M}]]^{|M|} \to C[[\mathfrak{M}]]$. We say that $\mathcal{M}$ is a multilinear type if

**MT1.** The constant mapping $\{0\} \mapsto f$ is in $\mathcal{M}$ for each $f \in C[[\mathfrak{M}]]$.

**MT2.** The $i$-th projection mapping $\pi_i: C[[\mathfrak{M}]]^{|M|} \to C[[\mathfrak{M}]]$ is in $\mathcal{M}$ for $i = 1, \ldots, |M|$.

**MT3.** The multiplication mapping from $C[[\mathfrak{M}]]^2$ into $C[[\mathfrak{M}]]$ is in $\mathcal{M}$.

**MT4.** If $M, N_1, \ldots, N_{|M|} \in \mathcal{M}$, then $M \circ \prod_{i=1}^{|M|} N_i \in \mathcal{M}$.

Given subsets $\mathfrak{V}_1, \ldots, \mathfrak{V}_v, \mathfrak{W}_1, \ldots, \mathfrak{W}_w$ of $\mathfrak{M}$, we say that a strongly multilinear mapping

$$M: C[[\mathfrak{V}_1]] \times \cdots \times C[[\mathfrak{V}_v]] \to C[[\mathfrak{W}_1]] \times \cdots \times C[[\mathfrak{W}_w]]$$

is of type $\mathcal{M}$, if for $i = 1, \ldots, w$, there exists a mapping $\pi_i: C[[\mathfrak{V}_i]]^w \to C[[\mathfrak{W}_i]]$ in $\mathcal{M}$, such that $\pi_i \circ M$ coincides with the restriction of the domain and image of $\pi_i$ to $C[[\mathfrak{V}_i]] \times \cdots \times C[[\mathfrak{V}_v]]$ resp. $C[[\mathfrak{W}_i]]$. We say that a Noetherian operator

$$\Phi: C[[\mathfrak{V}_1]] \times \cdots \times C[[\mathfrak{V}_v]] \to C[[\mathfrak{W}_1]] \times \cdots \times C[[\mathfrak{W}_w]]$$

is of type $\mathcal{M}$, if it admits a multilinear decomposition consisting of strongly multilinear mappings of type $\mathcal{M}$ only. In examples 30 and 31, we may then replace “Noetherian operator” by “Noetherian operator of type $\mathcal{M}$”.

Example 32. For any set $S$ of strongly linear mappings $C[[\mathfrak{M}]] \to C[[\mathfrak{M}]]$, there exists a smallest multilinear type $\mathcal{M} = \langle S \rangle$ which contains $S$. Taking $\mathfrak{T} = C[[\mathfrak{M}]]$ to be the field of transseries whose logarithmic and exponential depths are bounded by $\omega$, interesting special cases are obtained when taking $S = \{ \partial \}$ or $S = \{ f \}$. Noetherian operators of type $\langle \{ \partial \} \rangle$ resp. $\langle \{ f \} \rangle$ may then simply be called differential resp. integral Noetherian operators. Given a finite subset $g_1, \ldots, g_n$ of positive infinitely large transseries in $\mathfrak{T}$, another interesting case is obtained by taking $S = \{ o_{g_1}, \ldots, o_{g_n} \}$, where $o_{g_i}$ stands for right composition with $g_i$. 
5.2 Combinatorial representations of Noetherian operators

Let $\Phi: C[[M]] \to C[[M]]$ be a Noetherian operator with a multilinear decomposition $(M_i)_{i \in I}$. Then $\Phi$ is uniquely determined by the action of the $M_i$ on monomials in $M$. For the deeper theory of Noetherian operators, it is convenient to represent this action in a combinatorial way.

Abstractly speaking, a set of $M$-labeled structures is a set $\Sigma$, together with a map that assigns to each $\sigma \in \Sigma$ a labeling $\sigma \cdot | \{1, \ldots, |\sigma|\} \to M; p \mapsto \sigma[p]$, where $|\sigma| \in N$ stands for the size or arity of $\sigma$; for simplicity, we denote such a set of $M$ labeled structures also by $\Sigma$. For each subset $\mathcal{S}$ of $M$, we denote the subset of $\mathcal{S}$-labeled structures in $\Sigma$ by

$$\Sigma_{\mathcal{S}} = \{\sigma \in \Sigma | \text{im} \sigma[\cdot] \subseteq \mathcal{S}\}.$$  

We strictly order couples in $\Sigma \times M$ by $(\sigma, m) \succ (\sigma', m') \iff m \succ m'$. A mapping $\theta: \Sigma \to \mathcal{P}(M)$ is called a choice operator. We say that $\theta$ is Noetherian, if for any Noetherian subset $\mathcal{S}$ of $M$, the subset

$$\{(\sigma, m) | \sigma \in \Sigma_{\mathcal{S}} \land m \in \theta(\sigma)\}$$

of $\Sigma \times M$ is Noetherian.

Example 33. Let $f: M^m \to M$ be a strictly increasing $m$-ary operation and let $\Sigma = M^m$, with $(x_1, \ldots, x_m)[p] = x_p$ for all $x_1, \ldots, x_m \in M$ and $1 \leq p \leq m$. Then $\theta: \Sigma \to \mathcal{P}(M); (x_1, \ldots, x_m) \mapsto \{f(x_1, \ldots, x_m)\}$ is a Noetherian choice operator.

Figure 1. Graphical representation of the action of $\theta^M$ on the structure $\sigma \in \Sigma^M$ with input $(e^{-e^1}, e^{-e^2})$, for the strongly bilinear operator $M$: $(f, g) \mapsto f \cdot g$. Notice that $\int e^{-2i^1} = e^{-2i^2}(-\frac{1}{2}e^{i^1} + \frac{1}{4}e^{i^2} - \frac{1}{8}e^{i^3} + \frac{3}{16}e^{i^4} + \cdots)$.

Returning to our Noetherian operator $\Phi$, we may see each tuple $\sigma = (i, m_1, \ldots, m_{|i|})$ as an $M$-labeled combinatorial structure with $|\sigma| = |i|$ and $\sigma[p] = m_p$ for all $1 \leq p \leq |\sigma|$. Let $\Sigma = \Sigma^\Phi$ denote the set of such structures. We get a natural Noetherian choice operator $\theta = \theta^\Phi: \Sigma \to \mathcal{P}(M)$ by taking $\theta(\sigma) = \text{supp} M_i(m_1, \ldots, m_{|i|})$. Graphically speaking (see figure 1), we may represent the action of $\theta$ on $\sigma$ by a box with (a tuple of) “inputs” in $M$ and (a set of) “outputs” in $\mathcal{S}$.

Inversely, given a Noetherian choice operator $\theta: \Sigma \to \mathcal{P}(M)$ and an operator $\Theta: \Sigma \to C[[M]]$ with $\text{supp} \Theta(\sigma) \subseteq \theta(\sigma)$ for all $\sigma \in \Sigma$, we define a Noetherian operator by

$$\Phi(f) = \sum_{\sigma \in \Sigma} \left( \prod_{p=1}^{|\sigma|} f_{\sigma[p]} \right) \Theta(\sigma). \quad (6)$$
As to its multilinear decomposition, we associate an $M_\sigma: C[[\mathfrak{M}]]^{|\sigma|} \rightarrow C[[\mathfrak{M}]]$ to each $\sigma \in \Sigma$ by

$$M_\sigma(f_1, \ldots, f_{|\sigma|}) = \left( \prod_{p=1}^{|\sigma|} f_{p, \sigma[p]} \right) \Theta(\sigma).$$

For Noetherian families $(f_i)_{i \in I} \in C[[\mathfrak{M}]]^I$, we indeed have

$$\Phi \left( \sum_{i \in I} f_i \right) = \sum_{\sigma \in \Sigma} \left( \prod_{p=1}^{|\sigma|} \sum_{i \in I} f_{i, \sigma[p]} \right) \Theta(\sigma)$$

$$= \sum_{\sigma \in \Sigma} \left( \prod_{p=1}^{|\sigma|} f_{i, \sigma[p]} \right) \Theta(\sigma)$$

$$= \sum_{\sigma \in \Sigma} M_\sigma(f_{i_1}, \ldots, f_{i_{|\sigma|}}),$$

since for each $\sigma \in \Sigma$, there are only finitely many tuples $(i_1, \ldots, i_{|\sigma|}) \in I^{|\sigma|}$, such that $\prod_{p=1}^{|\sigma|} f_{i_p, \sigma[p]} \neq 0$.

### 5.3 Composition of choice operators

In example 31, we have shown that the composition of two Noetherian operators $\Phi: C[[\mathfrak{M}]] \rightarrow C[[\mathfrak{M}]]$ and $\Psi: C[[\mathfrak{M}]] \rightarrow C[[\mathfrak{M}]]$ is again Noetherian. Let us now show how to interpret the composition $\Psi \circ \Phi$ in a combinatorial way. Denote the natural choice operators associated to $\Phi$ and $\Psi$ by $\theta: \Sigma \rightarrow \mathcal{P}(\mathfrak{M})$ resp. $\xi: T \rightarrow \mathcal{P}(\mathfrak{M})$. We first define the composition $\xi \circ \theta: \Upsilon \rightarrow \mathcal{P}(\mathfrak{M})$ of the choice operators $\xi$ and $\theta$. Then $\Phi, \Psi$ and $\Psi \circ \Phi$ will be given by (6) and similar formulas, for certain mappings $\Theta: \Sigma \rightarrow C[[\mathfrak{M}]]$, $\Xi: T \rightarrow C[[\mathfrak{M}]]$ resp. $\Xi \circ \Theta: \Upsilon \rightarrow C[[\mathfrak{M}]]$. Here we may assume that $\Theta$ and $\Xi$ are given and we have to construct $\Xi \circ \Theta$.

Let $\tau \in T$ be given together with a tuple $\sigma = (\sigma_1, \ldots, \sigma_{|\tau|}) \in \Sigma^{|\tau|}$, such that $\tau[q] \in \theta(\sigma_q)$ for each $1 \leq q \leq |\tau|$. Then these data determine a unique $\mathfrak{M}$-labeled structure $v = \tau[\sigma]$, with $|v| = \sum_{q=1}^{|\tau|} |\sigma_q|$ and $v[p + \sum_{r=1}^{q-1} |\sigma_r|] = \sigma_q[p]$, for all $1 \leq q \leq |\tau|$ and $1 \leq p \leq |\sigma_q|$. We define $\Upsilon$ to be the set of all such combinatorial structures (see figure 2). Then we claim that the choice operator $\xi \circ \theta: \Upsilon \rightarrow \mathcal{P}(\mathfrak{M})$; $\tau[\sigma] \mapsto \xi(\tau)$ is Noetherian.

So let $\mathfrak{F}$ be a Noetherian subset of $\mathfrak{M}$. We will prove that for any sequence $x_1 = (\tau_1[\sigma_1], v_1), x_2 = (\tau_2[\sigma_2], v_2), \ldots$ of elements in the set

$$\{ (\tau[\sigma], v) \mid \tau[\sigma] \in \Upsilon_{\mathfrak{F}} \cap v \in \xi(\tau) \},$$

there exist $i < j$ with $(\tau_i[\sigma_i], v_i) \succ (\tau_j[\sigma_j], v_j)$. Since $\theta$ is Noetherian, $\Sigma = \bigcup_{\sigma \in \Sigma} \theta(\sigma)$ is a Noetherian subset of $\mathfrak{M}$, and we observe that $\tau \in T_{\Sigma}$ for each $\tau[\sigma] \in \Upsilon_{\mathfrak{F}}$. Since $\xi$ is Noetherian, we may therefore assume that $(\tau_1, v_1) \succ (\tau_j, v_j)$, modulo the extraction of a subsequence. If $v_i \succ v_j$ for some $i < j$, then we have $(\tau_i[\sigma_i], v_i) \succ (\tau_j[\sigma_j], v_j)$ and we are done. Hence, we may assume that $(\tau_1, v_1) = (\tau_2, v_2) = \ldots$. We conclude by the observation that given $\tau \in T$ there exist only a finite number of $\sigma_q \in \Sigma_{\mathfrak{F}}$ with $\tau[q] \in \Theta(\sigma_q)$, since $\theta$ is Noetherian.
Now consider the operator $\Xi \circ \Theta : \Upsilon \to C[[\mathfrak{M}]]$; $\tau[\sigma] \mapsto \left( \prod_{q=1}^{\left| \tau \right|} \Theta(\sigma_q)_{\tau[q]} \right) \Xi(\tau)$. Clearly, $\text{supp} \left( \Xi \circ \Theta \right)(\upsilon) \subseteq (\xi \circ \theta)(\upsilon)$ for all $\upsilon \in \Upsilon$. We claim that

$$
(\Psi \circ \Phi)(f) = \sum_{\upsilon \in \Sigma \circ \theta} \left( \prod_{r=1}^{\left| \upsilon \right|} f_{\upsilon[r]} \right) \left( \Xi \circ \Theta \right)(\upsilon),
$$

for all $f \in C[[\mathfrak{M}]]$. Indeed,

$$
(\Psi \circ \Phi)(f) = \sum_{\tau \in T} \left( \prod_{q=1}^{\left| \tau \right|} \Phi(f)_{\tau[q]} \right) \Xi(\tau)
$$

$$
= \sum_{\tau \in T} \left[ \prod_{q=1}^{\left| \tau \right|} \left( \sum_{\sigma_q \in \Sigma_{\sigma_q}} \left( \prod_{p=1}^{\left| \sigma_q \right|} f_{\sigma_q[p]} \right) \Theta(\sigma_q)_{\tau[q]} \right) \right] \Xi(\tau)
$$

$$
= \sum_{\upsilon \in \Sigma \circ \theta} \left( \prod_{r=1}^{\left| \upsilon \right|} f_{\upsilon[r]} \right) \left( \Xi \circ \Theta \right)(\upsilon).
$$

This yields the desired combinatorial description of the composition $\Psi \circ \Phi$.

Figure 2. Illustration of the action of $\xi \circ \theta$ on a structure $\tau[\sigma_1, \sigma_2, \sigma_3]$ in $\Upsilon$. For each $\sigma_i$ that we attach to $\tau$, we require the “output” of $\sigma_i$ to coincide with the “input” of $\tau$.

5.4 Canonical multilinear decompositions

We already noticed that each Noetherian operator $\Phi : C[[\mathfrak{M}]] \to C[[\mathfrak{M}]]$ has a multilinear decomposition of the form $(M_i)_{i \in \mathbb{N}}$, such that $M_i$ has arity $i$ for each $i \in \mathbb{N}$. Setting $\Phi_i = M_i(f, \ldots, f)$ for all $f$ and $i$, we then have

$$
\Phi = \Phi_0 + \Phi_1 + \Phi_2 + \ldots
$$

(8)
Now assume that \( C \supseteq \mathbb{Q} \) (so that \( C \) is in particular torsion-free). Then, modulo replacing each \( \Phi_i \) by the operator \( \tilde{\Phi}_i \) with

\[
\tilde{\Phi}_i(f_1, \ldots, f_i) = \frac{1}{i!} \sum_{\sigma \in \mathcal{S}_i} \Phi_i(f_{\sigma(1)}, \ldots, f_{\sigma(i)}),
\]

we may assume without loss of generality that the \( \Phi_i \) are symmetric. Under this additional symmetry assumption, the decomposition (8) is actually unique, and we call \( \Phi_i \) the homogeneous part of \( \Phi \) of degree \( i \).

**Proposition 34.** Let \( \Phi: C[[\mathcal{M}]]^i \to C[[\mathcal{M}]] \) be a Noetherian operator with a multilinear decomposition \( (M_i)_{i \in \mathbb{N}} \), such that \( M_i \) is symmetric and of arity \( i \) for each \( i \in \mathbb{N} \). If \( C \) is torsion-free and \( \Phi = 0 \), then \( M_i = 0 \) for each \( i \in \mathbb{N} \).

**Proof.** We observe that it suffices to prove that \( \Phi_i = 0 \) for each \( i \in \mathbb{N} \), since the \( M_i \) are symmetric and \( C \) is torsion-free. Assume the contrary and let \( f \in C[[\mathcal{M}]] \) be such that \( \Phi_i(f) \neq 0 \) for some \( i \). Choose \( m \in \mathcal{S} = \bigcup_{i \in I} \text{supp } \Phi_i(f) \neq \emptyset \) is Noetherian. The Noetherianity of \( (\Phi_i(f))_{i \in \mathbb{N}} \) implies that there exist only a finite number of indices \( i \), such that \( m \in \text{supp } \Phi_i(f) \). Let \( i_1 < \cdots < i_n \) be those indices.

Let \( c_k = \Phi_{i_k}(f)^m \) for all \( k \in \{1, \ldots, n\} \). For any \( l \in \{1, \ldots, n\} \), we have \( \Phi_{i_k}(l f)^m = l^{i_k} c_k \), by multilinearity. On the other hand, \( \Phi(l f)^m = \Phi_{i_1}(l f)^m + \cdots + \Phi_{i_n}(l f)^m = 0 \) for each \( l \), so that

\[
\begin{pmatrix}
1 \\
\vdots \\
1
\end{pmatrix}
= 
\begin{pmatrix}
\nu^{i_1} & \cdots & \nu^{i_n}
\end{pmatrix}
\begin{pmatrix}
c_1 \\
\vdots \\
c_n
\end{pmatrix}
= 0.
\]

The matrix on the left hand side admits an inverse with rational coefficients (indeed, by the sign rule of Descartes, a real polynomial \( \alpha_1 x^{i_1} + \cdots + \alpha_n x^{i_n} \) cannot have \( n \) distinct positive zeros unless \( \alpha_1 = \cdots = \alpha_n = 0 \)). Consequently, an integer multiple of the vector on the right hand side vanishes. We infer that \( c_1 = \cdots = c_n = 0 \), since \( C \) is torsion-free. This contradiction completes the proof. \( \square \)

6 The algebraic implicit function theorem

Let \( \mathcal{M} \) and \( \mathcal{R} \) be monomial sets and let \( \Phi: C[[\mathcal{M}]] \times C[[\mathcal{R}]] \to C[[\mathcal{M}]], (f, g) \mapsto \Phi(f, g) \) be a Noetherian operator. We call \( \Phi \) strictly extensive in \( f \) if there exists a multilinear decomposition \( (M_i)_{i \in I} \) of \( \Phi \), such that for all \( i, (\nu_1, \ldots, \nu_{|i|}) \in (\mathcal{M} \times \mathcal{R})^{\{1\}}, 1 \leq j \leq |i| \) and \( m \in \text{supp } M_i(\nu_1, \ldots, \nu_{|i|}) \), we have \( \nu_j \in \mathcal{M} \Rightarrow m \prec \nu_j \). In particular, such a \( \Phi \) is contracting in \( f \). The main objective of this section will be to prove the following theorem:

**Theorem 35.** Let \( \Phi: C[[\mathcal{M}]] \times C[[\mathcal{R}]] \to C[[\mathcal{M}]], (f, g) \mapsto \Phi(f, g) \) be a Noetherian operator, which is strictly extensive in \( f \). Then for each \( g \in C[[\mathcal{R}]] \) the operator \( \Phi(\cdot, g) \) on \( C[[\mathcal{M}]] \) has a unique fixed point \( \Psi(g) \), and the operator \( \Psi: C[[\mathcal{R}]] \to C[[\mathcal{M}]] \) is Noetherian.

6.1 Iteration of choice operators with parameters

Let \( \Phi: C[[\mathcal{M}]] \times C[[\mathcal{R}]] \to C[[\mathcal{M}]] \) be as in theorem 35 and let \( \theta: \Sigma \to \mathcal{P}(\mathcal{M}) \) be the natural Noetherian choice operator associated to \( \Phi \). The fact that \( \Phi \) is strictly extensive in \( f \) implies that \( \theta \) may be assumed to be strictly extensive on \( \mathcal{M} \), i.e.

\[
\forall \sigma \in \Sigma, \forall m \in (\text{im } \sigma[\cdot] \cap \mathcal{M}), \forall n \in \theta(\sigma), n \prec m.
\]

Also, let \( i: \Delta_\mathcal{M} \to \mathcal{P}(\mathcal{R}) \) be the natural Noetherian choice operator associated to the identity mapping \( \text{Id}_\mathcal{M}: C[[\mathcal{M}]] \to C[[\mathcal{M}]] \). Actually, we take \( \Delta_\mathcal{M} = \{\delta_n \mid n \in \mathcal{M}\} \), with \( |\delta_n| = 1, \delta_n[1] = n \) and \( i(\delta_n) = \{n\} \) for all \( n \in \mathcal{M} \).
Now consider the sets $T = \Pi_{h \in \mathcal{N}} T_h$ of $(\mathfrak{M} \amalg \mathfrak{N})$-labeled combinatorial structures, where the $T_d$ are defined by

$$
T_0 = \Sigma_{\mathfrak{N}}; \quad T_{d+1} = (\Sigma \amalg \Sigma_{\mathfrak{N}}) \circ (T_d \Pi \Delta_{\mathfrak{N}}).
$$

For each $\tau \in T$, the minimal $d \in \mathbb{N}$ with $\tau \in T_d$ is called the depth of $\tau$. We have a natural choice operator $\xi: T \to \mathcal{P}(\mathfrak{N})$, which is defined componentwise by

$$
\xi|_{T_0} = \theta|_{\Sigma_{\mathfrak{N}}}; \quad \xi|_{T_{d+1}} = \theta|_{\Sigma \amalg \Sigma_{\mathfrak{N}}} \circ (\xi|_{T_d} \Pi \Delta_{\mathfrak{N}}).
$$

Here $\xi|_{T_d} \Pi \xi|_{\Delta_{\mathfrak{N}}}: T_d \Pi \Delta_{\mathfrak{N}} \to \mathcal{P}(\mathfrak{M} \amalg \mathfrak{N})$ stands for the choice operator which coincides with $\xi$ on $T_d$ and with $\epsilon$ on $\Delta_{\mathfrak{N}}$. Similarly, the componentwise definition of $\xi$ means that we take $\xi = \bigcup_{d \in \mathbb{N}} \xi|_{T_d}$. In figure 3 one finds an illustration of the action of $\xi$ on a structure in $T$. We will also call $\theta^{*,\mathfrak{N}}$ the iteration of $\theta$ with parameters in $\mathfrak{N}$.

**Figure 3.** Illustration of the action of the iterated choice operator $\xi = \theta^{*,\mathfrak{N}}$ on a structure in $T = \Sigma^{*,\mathfrak{N}}$. The connected “inputs” and “outputs” should match in a similar way as in figure 2. The white and black dots correspond to monomials in $\mathfrak{M}$ resp. $\mathfrak{N}$.

**Theorem 36.** Let $\Sigma$ be a set of $(\mathfrak{M} \amalg \mathfrak{N})$-labeled structures and $\theta: \Sigma \to \mathcal{P}(\mathfrak{N})$ a Noetherian choice operator which is extensive on $\mathfrak{M}$. Then $\theta^{*,\mathfrak{N}}$ is Noetherian.

**Proof.** Let $\mathfrak{A}$ be a Noetherian subset of $\mathfrak{N}$. Assume that there exists a bad sequence

$$
(v_1, m_1), (v_2, m_2), \ldots, \quad (9)
$$

with $v_i \in T_{\mathfrak{A}}$ and $m_i \in \xi(\tau_i)$ for each $i$. We may assume that we have chosen this bad sequence minimally in the sense that the depth of each $v_i$ is minimal in the set of all bad sequences with fixed $(v_1, m_1), \ldots, (v_{i-1}, m_{i-1})$. Writing $v_i = \sigma_i[\tau_{i,1}, \ldots, \tau_{i,|\sigma_i|}]$ for each $i$, we claim that the induced ordering on $\mathfrak{B} = \{(\tau_{i,j}, m_{i,j})| i \in \mathbb{N} \land 1 \leq j \leq |\tau_i| \land m_{i,j} \in \xi(\tau_{i,j})\}$ is Noetherian.

Indeed, suppose for contradiction that the claim is false, and let

$$(\tau_{i1,j1}, m_{i1,j1}), (\tau_{i2,j2}, m_{i2,j2}), \ldots$$

be a bad sequence. Notice that $(\tau_{ik,jk}, m_{ik,jk}) \prec (v_{ik}, m_{ik})$ for all $k$, since $\theta$ is strictly extensive on $\mathfrak{M}$. Hence, taking $k$ such that $i_k$ is minimal, the sequence

$$(v_1, m_1), \ldots, (v_{ik-1}, m_{ik-1}), (\tau_{ik,jk}, m_{ik,jk}), (\tau_{ik+1,jk+1}, m_{ik+1,jk+1}), \ldots$$

is bad, contradicting the minimality of $v_i$.
is also bad. This contradicts the minimality of (9).

At this point we have proved that $\mathfrak{B}$ is Noetherian. In particular, $\mathfrak{B} = \{w \mid (v, w) \in \mathfrak{B}\}$ is Noetherian. Hence, there exist $i_1 > i_2 \cdots$ with $(\sigma_{i_1}, m_{i_1}) \gg (\sigma_{i_2}, m_{i_2}) \gg \cdots$, since $\sigma_{i_1}, \sigma_{i_2} \cdots \in \Sigma[[\mathfrak{W}]]$. If $m_{i_m} > m_n$ for some $m > n$, then $(v_{i_m}, m_{i_m}) \gg (v_{i_n}, m_{i_n})$ and we are done. Otherwise, $(\sigma_{i_1}, m_{i_1}) = (\sigma_{i_2}, m_{i_2}) = \cdots$. Now for every $1 \leq p \leq |\sigma_{i_1}|$, the $(\tau, n) \in \mathfrak{B} \cap \{0 = n\}$ with $w = \sigma_{i_1}[p]$ are finite in number, since they form an antichain. Consequently, $v_{i_1}, v_{i_2}, \ldots$ can only take a finite number of values and there exist $m < n$ with $(v_{i_m}, m_{i_m}) = (v_{i_n}, m_{i_n})$. This contradicts the badness of (9). □

6.2 Proof of the implicit function theorem

With the notations from the previous section, let $\Theta: \Sigma \to C[[\mathfrak{W}]]$ be a mapping, such that $\text{supp} \Theta(\sigma) \subseteq \theta(\sigma)$ for all $\sigma \in \Sigma$, and such that (6) holds for all $f \in C[[\mathfrak{W}]] \times [[\mathfrak{W}]]$. We now define $\Xi: T \to C[[\mathfrak{W}]]$ componentwise as follows:

$$
\Xi|_{T_0} = \Theta|_{\Sigma_0};
\Xi|_{T_{d+1}} = \Theta|_{\Sigma \setminus \Sigma_0} \circ (\Xi|_{T_d} \Xi|_{\Delta_0}),
$$

where $I_{|\Delta_0}; \Delta_0 \to C[[\mathfrak{W}]]; \delta_n \to n$. Theorem 36 implies that we may define a function $\Psi: C[[\mathfrak{W}]] \to C[[\mathfrak{W}]]$ by the formula

$$
\Psi(g) = \sum_{\tau \in T} \left(\prod_{p=1}^{\tau} g_{\tau[p]}\right) \Xi(\tau).
$$

(10)

We can now prove the following more explicit version of the implicit function theorem.

**Theorem 37.** Let $\Phi: C[[\mathfrak{W}]] \times C[[\mathfrak{W}]] \to C[[\mathfrak{W}]]$, $(f, g) \mapsto \Phi(f, g)$ be a Noetherian operator, which is strictly extensive in $f$. Then the Noetherian operator $\Psi: C[[\mathfrak{W}]] \to C[[\mathfrak{W}]]$ defined by (10) is unique with the property that $\Psi(g) = \Phi(\Psi(g), g)$ for all $g \in C[[\mathfrak{W}]]$.

**Proof.** Identifying $C[[\mathfrak{W}]] \times C[[\mathfrak{W}]]$ and $C[[\mathfrak{W} \circ \mathfrak{W}]]$ via the natural isomorphism, we have

$$(\Psi(g), g) = \Psi(g) + g = \sum_{\tau \in \text{TII}_{\Delta_0}} \left(\prod_{q=1}^{\tau} g_{\tau[q]}\right) (\Xi \text{TII})(\tau),$$

for all $g \in C[[\mathfrak{W}]]$. Similarly, for all $(f, g) \in C[[\mathfrak{W}]] \times C[[\mathfrak{W}]]$, we have

$$
\Phi_{\text{rest}}(f, g) = \Phi(f, g) - \Phi(0, g) = \sum_{\sigma \in \Sigma \setminus \Sigma_0} \left(\prod_{p=1}^{\sigma} (f + g)_{\sigma[p]}\right) (\Theta|_{\Sigma \setminus \Sigma_0})(\sigma).
$$

Applying (7), we conclude that

$$
\Psi(g) = \sum_{\tau \in T_0} \left(\prod_{q=1}^{\tau} g_{\tau[q]}\right) \Xi(\tau) + \sum_{\tau \in \text{TII}_0} \left(\prod_{q=1}^{\tau} g_{\tau[q]}\right) \Xi(\tau) = \sum_{\tau \in \text{TII}} \left(\prod_{q=1}^{\tau} g_{\tau[q]}\right) (\Theta|_{\Sigma \setminus \Sigma_0} \circ (\Xi|_{\text{TII}_{\Delta_0}}))(\tau) = \Phi(0, g) + \Phi_{\text{rest}}(\Psi(g), g) = \Phi(\Psi(g), g),
$$

as desired.
for all $g \in C[[\mathfrak{M}]]$. The uniqueness of $\Psi$ follows in the same way as in the proof of theorem 23, since $\Phi$ is contracting in $f$. 

\textbf{Corollary 38.} Let $\mathcal{M}$ be a multilinear type. If $\Phi$ is of type $\mathcal{M}$ in theorem 35, then so is $\Psi$. 

\textbf{6.3 Applications}

\textbf{Example 39.} Let us first show that the classical implicit function theorem for bivariate power series follows from theorem 23. So let $f = \sum_{i,j} f_{i,j} v^i u^j \in C[[v, u]]$ be a bivariate power series with $f_{0,0} = 0$ and $f_{1,0} \neq 0$. Then we have to prove that there exists a unique power series $g \in u C[[u]]$ with

$$f(g(u), u) = 0.$$ 

Modulo division of $f$ by $f_1 = \sum_j f_{1,j} u^j$ and passing $f_1$ to the other side of the equation, the problem can be reduced to solving the equation

$$g(u) = f(g(u), u)$$

for $f \in C[[v, u]]$ with $f_{0,0} = f_{1,0} = 0$. Under these assumptions, the series $f$ corresponds to an operator $\Phi: u C[[u]] \times \{0\} \to u C[[u]]; (g, 0) \mapsto f(g, u) = \sum_{i,j} f_{i,j} g(u)^i v^j$. Theorem 23

then provides us with a unique mapping $\Psi: \{0\} \to u C[[v]]$ with $\Psi(0) = \Phi(\Psi(0), 0)$. Taking $g = \Psi(0)$, we thus find the unique solution to (11).

Moreover, theorem 37 actually tells us that the “natural solution” to (11), which is obtained by recursively plugging in the left hand side of the equation in the right hand side, is indeed a solution. We also notice that by applying theorem 37 to the operator

$$\Phi: u C[f_1][[u]] \times \{0\} \to u C[f_1][[u]]; (g, 0) \mapsto f(g, u) = \sum_i f_i g(u)^i$$

instead of the previous $\Phi$, we actually get a solution $g(u)$ in terms of the coefficients of $f$.

\textbf{Example 40.} The above example naturally generalizes to the multivariate case. What is more, we may consider non commutative power series in several variables. Given symbols $u_1, \ldots, u_n$, we order the free monomial monoid $\{u_1, \ldots, u_n\}^*$ in $u_1, \ldots, u_n$ by the ordering $\succeq$ from example 1.4. Then the ring of non commutative power series in $u_1, \ldots, u_n$ over $C$ is given by $C\langle\langle u_1, \ldots, u_n\rangle\rangle = C[[\{u_1, \ldots, u_n\}^*]]$. Now consider the equation

$$g(u_1, \ldots, u_n) = f(g(u_1, \ldots, u_n), u_1, \ldots, u_n),$$

(12)

for $f \in C[[v, u_1, \ldots, u_n]]$ with $f_1 = f_0 = 0$. Then it may be proved in a similar way as in the previous example that this equation admits a unique infinitesimal solution. Again, this solution is equal to the natural expression which is obtained when repeatedly plugging in the left hand side of (12) into the right hand side. Again, the solution may be expressed naturally in terms of the coefficients of the equation.

\textbf{Example 41.} Let $\mathbb{T} = C[[\mathfrak{M}]]$ be the field of transseries in $x$, whose logarithmic and exponential depths are bounded by some integer $d \in \mathbb{N}$ [vdH97]. The transseries $e^{-x^2} + e^{-e^x} + e^{-e^x/x} + \cdots$ is an example of an element in $\mathbb{T}$ if $d = 2$. Now consider the integral equation

$$f = g + \int f^2,$$

(13)
for $f, g \in \mathbb{T}$ and where $f, g \prec e^{-x}$. Taking $\mathcal{M} = \{ m \in \mathbb{M} | m \prec e^{-x} \}$ we may consider the operator $\Phi: C[[\mathbb{M}]] \times C[[\mathbb{M}]] \to C[[\mathbb{M}]]; (f, g) \mapsto g + f \cdot g^2$. Theorem 23 then implies that there exists a unique function $\Psi: C[[\mathbb{M}]] \to C[[\mathbb{M}]]$, such that $f = \Psi(g)$ satisfies (13) for all $g \in C[[\mathbb{M}]]$. Theorem 37 and its corollary imply that $\Psi$ is actually an integral Noetherian operator. Modulo regrouping terms, this means that the series

$$f = g + f \cdot g^2 + 2f \cdot g \cdot g^2 + 4f \cdot g \cdot g^2 + f \cdot (g^2)^2 + \ldots$$

is indeed a solution to (13) for all $g \in C[[\mathbb{M}]]$.

**Example 42.** Let $\mathbb{T} = C[[\mathbb{M}]]$ now be the field of transseries in $x$, whose exponential and logarithmic depths are bounded by $\omega$. Consider the functional equation

$$f(x) = g(x) + h(x) \cdot f(x^2) + f'(e^{x^2})$$

(14)

for $f, g, h \in \mathbb{T}$ and $f, g, h \prec e^{-x}$. Taking $\mathcal{M} = \{ m \in \mathbb{M} | m \prec e^{-x} \}$, theorem 37 yields a Noetherian operator $\Psi: C[[\mathbb{M}]] \times C[[\mathbb{M}]] \to C[[\mathbb{M}]]; (g, h) \mapsto \Psi(g, h)$, such that $f(x) = \Psi(g, h)$ is a solution to (14). Moreover, $\Psi$ is what one could call a “differential compositional Noetherian operator”.

**Example 43.** For independent infinitely large variables $x, y \succ 1$ consider the monomial group

$$\mathcal{M} = x^R y^R e^{-x^R} e^{y^R} e^{-x^R + y^R}$$

and its subset

$$\mathcal{M} = x^R y^R e^{-x^R} e^{y^R} e^{-x^R + y^R}.$$ 

Then the equation

$$f = e^{-x^R + y} + \frac{\partial f}{\partial x} \frac{\partial f}{\partial y} + e^{-x - 3y} \frac{\partial^2 f}{\partial x^2} \frac{\partial^2 f}{\partial x \partial y}$$

admits a unique solution $f \in \mathbb{R}[[\mathbb{M}]]$, which can be expressed as a “partial differential series”. Theorem 23 can not be directly applied in this case.
